CHAPTER 1 - COURSE INTRODUCTION

COURSE OBJECTIVES

- ✧ Describe how Struts fit in a Java application server environment.
- ✧ Use Struts to implement an MVC web application design.
- ✧ Configure a Struts application using *struts-config.xml* and *web.xml*.
- ✧ Build a JSP view using Struts and JSTL tags.
- ✧ Handle form validation, error processing, and logging in a Struts environment.
- ✧ Use the Struts Tiles facilities to make the look and feel of a web application flexible and easy to maintain.

COURSE OVERVIEW

- * **Audience:** Experienced Java Servlet and JSP developers who need to use Struts as a framework for MVC web application development.
- * **Prerequisites:** *Java Programming* and *Java Web Programming*.
- * **Classroom Environment:**
 - A workstation per student.

USING THE WORKBOOK

This workbook design is based on a page-pair, consisting of a Topic page and a Support page. When you lay the workbook open flat, the Topic page is on the left and the Support page is on the right. The Topic page contains the points to be discussed in class. The Support page has code examples, diagrams, screen shots and additional information. **Hands On** sections provide opportunities for practical application of key concepts. **Try It** and **Investigate** sections help direct individual discovery.

In addition, there is an index for quick look-up. Printed lab solutions are in the back of the book as well as on-line if you need a little help.

The Topic page provides the main topics for classroom discussion.

The Support page has additional information, examples and suggestions.

Topics are organized into first (*), second (➤) and third (▪) level points.

JAVA SERVLETS

THE SERVLET LIFE CYCLE

- * The servlet container controls the life cycle of the servlet.
 - When the first request is received, the container loads the servlet class
 - The container uses a separate thread to call
 - The container calls the destroy ()
- As with Java's finalize () method, don't count on this being called.
- * Override one of the init () methods for one-time initializations, instead of using a constructor.
 - The simplest form takes no parameters.

```
public void init () { ... }
```
 - If you need to know container-specific configuration information, use the other version.

```
public void init (ServletConfig config) { ... }
```
 - Whenever you use the ServletConfig approach, always call the superclass method, which performs additional initializations.

```
super.init (config);
```

Page 16

Rev 2.0.0

© 2002 ITCourseware, LLC

Pages are numbered sequentially throughout the book, making lookup easy.

CHAPTER 2

SERVLET BASICS

Hands On:

Add an init () method to your *Today* servlet that initializes along with the current date:

```
Today.java
...
public class Today extends GenericServlet {
    private Date bornOn;
    public void service(ServletRequest request,
        ServletResponse response) throws ServletException, IOException
    {
        ...
        Servlet was born on " + bornOn.toString();
        ... + today.toString();
    }
}
```

Code examples are in a fixed font and shaded. The on-line file name is listed above the shaded area.

Callout boxes point out important parts of the example code.

The init () method is called when the servlet is loaded into the container.

Screen shots show examples of what you should see in class.

STRUTS

CHAPTER 2 - STRUTS OVERVIEW

OBJECTIVES

- ✧ Describe how Struts fits into a Java web application.
- ✧ Identify the major components of the MVC Model 2 application design.
- ✧ Outline the basic flow through a web application using Struts.

WHAT IS STRUTS?

- ✧ Struts is an open source Java web application framework based on the Model-View-Controller design pattern.
 - It is based upon proven design patterns and published Java-based standards.
 - The name is a reference to the concept of struts in the architectural sense — struts form the skeleton of a building or bridge.
- ✧ Struts provides a solid basis for a framework that is easily extensible.
 - Struts framework classes can be easily extended to add or modify functionality.
- ✧ Struts facilitates change in web applications and specialization of development team members.
- ✧ Struts is an Apache Jakarta project sponsored by the Apache Software Foundation.
 - For more information, see: ***<http://struts.apache.org>***
- ✧ Struts uses Jakarta Commons projects, see: ***<http://jakarta.apache.org/commons/>***.
 - BeanUtils — JavaBean utility classes
 - Validator — Java and JavaScript form validation
 - Digester — An XML parser that facilitates the conversion of XML to objects
 - Collections — Some simple, fast collection utility classes
 - Logging — An interface to several prominent logging technologies

The Apache Struts project has been broken into two frameworks: Struts Action Framework and Struts Shale Framework.

The Struts Action Framework is the new name for what has traditionally been called Struts. It continues support and development on the request-based JSP framework that has been used in production since 2001. In this course, we will be studying the Struts Action Framework.

The Struts Shale Framework is a new project that builds on five years of learning and technology advances. It embraces the JavaServer Faces (JSF) component model and allows for integration with other popular frameworks, such as Spring.

MODEL 1 DESIGN PATTERN

- ✴ Servlet and JSP development typically involves several technologies and skills:
 - Java
 - JSP
 - HTML, XHTML, XML, XSLT
 - CSS
 - JavaScript
- ✴ Co-mingling Java and JavaScript can make pages difficult to follow.
- ✴ Coupling business logic and presentation logic can also cause problems.
 - It is difficult to modify the website appearance.
 - Changes in business rules can necessitate retesting of the web application.
 - Embedded flow of control can be difficult to follow.
 - A web application is a more complex debugging environment.
- ✴ Servlets and JSPs make it easy to build simple inquiry sites.

MVC Model 1

MODEL 2 / MVC DESIGN PATTERN

✴ The *model*:

- Encapsulates the function of an application, including its internal state and actions to change its state.
- Typically knows nothing about the data presentation (view) or the application flow (control).
- Can use many Java-based technologies, such as JavaBeans, Enterprise JavaBeans, JDBC, etc.
- Components are not necessarily dependent upon a web container environment.

✴ The *view*:

- Is a presentation of the model.
- Retrieves data with the accessor methods of a model, but knows nothing about the controller.
- Should be notified when the model changes (state change).

✴ The *controller*:

- Reacts to user input and delegates the request.
- Creates and initializes the model with user information.
- Mediates flow, determining the flow required to handle a request.
- Is frequently directed by external configuration files, such as XML files.

A typical J2EE MVC application flow:

1. The browser makes an HTTP request. The web container forwards the request to the controller assigned to this kind of request.
2. The controller (usually a servlet), invokes business tier logic via the model. This may involve EJB and/or JDBC.
3. New or updated information is returned to the controller via the model.
4. The controller passes the new information to the appropriate view (usually a JSP).
5. The new view is returned to the browser via an HTTP response.

IMPLEMENTING MVC WITH A FRAMEWORK

- * Frameworks such as Struts provide a generic implementation of the MVC design pattern so that the developer can focus on the application requirements, rather than the MVC architecture.
- * Some functions of the framework:
 - To be declarative (XML) rather than code (Java) driven.
 - Map the incoming request to the application processing components.
 - Handle form input.
 - Provide error handling support.
 - Provide forwarding support, particularly for the view.
 - Provide for internationalization of views.
 - Assist in the development of a JSP.
 - Provide for user extensions.

THE STRUTS FRAMEWORK

- ✴ Struts is a group of configurable components designed for use in a Model 2 / MVC application design.
 - All parts of the Struts framework can be extended.
- ✴ The Struts controller is configurable.
 - The main controller is a Java servlet called **ActionServlet**.
 - It uses other controller component classes, including **RequestProcessor**, **ActionForm**, **ActionMapping**, **Action**, **ActionForward**, and **ActionError**.
- ✴ The Struts model interfaces with a user model.
 - There are no specific model components to Struts.
 - Struts can use existing Java-based technologies, such as JavaBeans, EJB, and JDBC.
 - There are typically beans that execute business logic and other beans that persist data.
- ✴ The Struts view is based on JSP technology.
 - View components are typically JSPs.
 - Struts includes extensive tag libraries and Velocity templates.
 - Struts can incorporate other web technologies, such as static template text (HTML, XML), dynamic content from other servlets and JSPs, and XSLT.

A typical J2EE Struts application flow:

1. The browser makes an HTTP request. The web container forwards the request to the Struts controller (**ActionServlet**). The **ActionServlet** passes the request to the appropriate **Action** that has been coded to deal with this request.
2. The **Action** invokes the business tier logic with the form bean (**ActionForm**). This may involve EJB and/or JDBC.
3. New or updated information is returned to the controller via the model (form bean).
4. The controller passes the new information (form beans and other JavaBeans) to the appropriate view (usually a JSP).
5. The new view is returned to the browser via an HTTP response.

BASIC STRUTS COMPONENTS

- ✴ An **ActionMapping** is an encapsulation of how an HTTP request path is mapped to a specific **Action**.
- ✴ An **ActionServlet** is an implementation of the command design pattern.
 - The user agent creates an HTTP event.
 - The web container creates an HTTP request and follows the mapping to the **ActionServlet**.
 - All of the processing for a web context goes through one **ActionServlet**.
- ✴ **ActionForm** beans, often called "form beans," mediate between the model and the view.
 - They are created and set by the controller.
 - They can contain validation.
 - They represent the request and response state, not the persistent business data.
- ✴ The controller passes the request, response, mapping information, and the form bean to the **execute()** method of your **Action** subclass.
 - Your **execute()** method should implement the business logic as a thin wrapper, or better still, act as a delegate to business beans.
 - Your implementation may act as an adapter that converts the form data and request into data that the business components expect.

BASIC STRUTS COMPONENTS (CONT'D)

- ✴ An **ActionForward** maps a logical name to a destination.
 - The **Action** determines what view or subsequent **Action** should get control next by requesting a symbolically-referenced **ActionForward**.
 - **ActionForwards** are configured in *struts-config.xml* and, thus, loosely coupled to the application.
- ✴ **ActionErrors** and **ActionMessages** contain lists of messages that can be passed to a view to be displayed with Struts tags.
- ✴ *struts-config.xml* contains configuration information for Struts, form beans, actions, mappings, forwarding, and exception handling.
- ✴ *web.xml* configures the **ActionServlet** and its servlet mapping, and locates the *struts-config.xml* file.
- ✴ Struts tag libraries assist in the preparation of a JSP view.

STRUTS DOCUMENTATION

- ✱ The struts documentation can be found online at [**http://struts.apache.org/struts-action/index.html**](http://struts.apache.org/struts-action/index.html).
- ✱ The User Guide contains the basic specifications for Struts.
 - General overview information on each of the components, and how to build the *struts-config.xml* file, can be found at [**userGuide/index.html**](#).
 - More detailed information is available in the JavaDoc API documentation.
- ✱ Struts FAQs and How to Guides contain useful links, samples, and answers to basic questions.
- ✱ There is separate documentation for the tag libraries and utilities.
 - It can be found at [**http://struts.apache.org/struts-taglib/index.html**](http://struts.apache.org/struts-taglib/index.html).
- ✱ Documentation for the Apache Foundation Commons Components, such as Logging and Validator, can be found at [**http://jakarta.apache.org/commons/index.html**](http://jakarta.apache.org/commons/index.html).
- ✱ You'll probably want documentation for Java and the web container, as well.

A STRUTS-BASED APPLICATION: LOGON

- * The client initiates a logon request.
- * The web container creates an **HttpServletRequest** object and passes it to *logon.jsp*.
- * The **HttpServletResponse** of the JSP returns a logon form.
- * The client completes the logon form (user and password parameters) and submits it to **/logon.do**.
- * The web container creates an **HttpServletRequest** object and follows a servlet mapping specified in *web.xml* to the **ActionServlet** (the Struts controller).
- * The controller creates an **ActionMapping** indicating that the request path was **/logon** and that control should go to the **LogonAction**, with its parameters saved in an instance of **LogonForm**.
 - This is often referred to as a *switchboard action*.
- * The **LogonAction execute()** method validates the logon.
 - If valid, control goes to a welcome page (*welcome.jsp*) logically specified in *struts-config.xml* as "success" after saving the user in the **HttpSession** object.
 - If invalid, an error message is added and control returns to the input page (*logon.jsp*) to be displayed on the logon page.
- * The valid (*welcome.jsp*) or invalid (*logon.jsp*) JSP is invoked by the web container and the response it generates is returned to the client.

Struts comes as a ZIP file that includes the documentation as a WAR file. You can access it through a web server or view it offline with a browser. To compile a Java component that uses Struts, several JAR files are needed in the classpath, including *struts.jar* and your application server's JAR file that contains the Servlet API. The Apache Commons packages have JARs that may be needed, as well.

To use Struts in a web application, *struts.jar* and other Common's JARs, such as *commons-logging.jar*, *commons-beanutils.jar*, and *commons-digester.jar*, from the `<strutsInstall>\lib` must be available to your application.

To simplify the building and deployment process, we will use the Apache Software Foundation's Ant tool. To use Ant, you create an XML configuration file called *build.xml* and define targets that define the steps for building and deploying your application. The targets also set dependencies, so that you can compile, build, and deploy with a single command.

For this class, we have provided *build.xml* files for you. They contain the proper classpath settings and targets for compiling the Java files, building the WAR file, and deploying the WAR file.

Try It:

To test the Logon application that is described on the previous page, perform the following steps:

1. Start your application server or web container.
2. Run the Ant command in the chapter directory.
3. Open a browser and go to ***http://localhost:port/Logon*** to retrieve a logon form.
4. Logon with **student** and **password**.
5. Try again with **student** and any invalid password.
6. Try again with your own name and password.

Your instructor will give you the details of how to start the server, run Ant, and which port to use within the URL.

LABS

- ❶ Use the Struts API documentation to answer the following questions:
 - a. What package contains **ActionServlet**, **ActionForm**, and **Action**?
 - b. What is the return type of the **Action execute()** method?
 - c. What is the signature of the **ActionForm validate()** method?
 - d. Where is information regarding the Struts Validator?
 - e. Does the Struts HTML tag library contain a **<hidden>** tag?(Solution: *lab1.txt*)
- ❷ Where is the *struts-config.xml* file located for the Logon application?
(Solution: *lab2.txt*)
- ❸ Look through the *struts-config.xml* file and see if you can determine where the text for the error messages used in the views of the logon application can be found.
(Solution: *lab3.txt*)
- ❹ Start a browser and enter ***http://localhost:port/Logon/***. Your instructor will tell you the correct port to use for your application server. How does it get to *logon.jsp*?
Hint: Look at *web.xml*.
(Solution: *lab4.txt*)
